# Setting up to pull documents from a job

You can set up to pull documents from a job, or suppress documents from printing, by doing the configuration tasks described in this section.

Before you do these tasks, read the usage scenarios for pulling documents from a job.

## In this section:

[Running the sample workflow for suppressing PDF documents](#)

The **PullPDFSample** workflow for suppressing the printing of PDF documents in a job illustrates how to use a list to control print suppression. The **PullPDFSample** workflow creates two child jobs which process the printed and suppressed documents separately.

[Running the sample workflow for suppressing AFP documents](#)

The **PullAFPSample** workflow for suppressing the printing of AFP documents in a job illustrates how to use a list to control print suppression. The **PullAFPSample** workflow creates two child jobs which process the printed and suppressed documents separately.

[Setting up a workflow that processes a pull list](#)

To extract documents from a job using a pull list, you set up a workflow that includes a step based on the **SetDocPropsFromList** step template. Additional steps and conditional processing (or additional workflows) are required to process both the documents extracted from the job and the documents remaining in the job.
